## Introduction

- A great challenge in the field of catalysis is the development of catalysts which possess the major advantages of both homogeneous (e.g., high activity, high selectivity, and mild reaction conditions) and heterogeneous (e.g., ease of catalyst recovery and high turnover numbers) catalysis.
- One way of bridging this 'gap' between homogeneous and heterogeneous catalysis is heterogenization of homogeneous catalysts.
- Heterogenization is achieved via either physisorption or through covalent grafting of a ligand or transition metal complex onto a solid support viz. Alumina, silica, MCM, carbon etc.,

## Methods of heterogenization of homogeneous catalyst

➤ **Generally the activity and selectivity of the homogeneous catalysts are changed (either it increases or decreases) after heterogenization. This may be due to the changes in geometry and electronic properties of the catalytic site.**

➤ **In order to study these changes in advance, prior to carry out this reaction in the laboratory, a theoretical study should be carried out. Moreover, these properties of a catalyst can be obtained computationally more easily than by experimental means.**

➤ **In the present work, the electronic and geometrical effects of anchoring bio-mimetic galactose oxidase catalyst onto oxidized carbon support is studied by a Density Functional Theory (DFT).**

## Computational Methods

**Program:** Gaussian 03

**Basis set :** 6-31G(d) for C, H, N and O

**Theory:** Density Functional Theory (DFT)

LanL2DZ for Cu

**Graphical user interface:** Gauss view 3.0

**Functional:** B3LYP hybrid

## Conclusion

The following results are obtained from DFT study upon anchoring the truncated models of galactose oxidase catalyst onto the hydroxyl functionalised carbon support,

- The bond lengths of Cu-N decreases whereas Cu-O increases.
- Inplane  $\angle$ N-Cu-N increases and  $\angle$ N-Cu-O,  $\angle$ O-Cu-O decreases. But out of plane  $\angle$ O- Cu-O increases.
- Percentage of metal orbital contribution to HOMO and LUMO energy level is low when compared to ligand orbitals. Hence redox properties of the catalyst is mostly ligand based rather than metal.
- Shifting of HOMO energy to less negative value and decreasing HOMO-LUMO energy gap indicates that the reducing capacity of the catalyst is still reduced and the oxidising capacity of the catalyst is increased by increasing the number of fused carbon rings in the carbon support.
