
Catalytic Partial Oxidation of low molecular-mass hydrocarbons

M. Baerns

Catalysis and Catalyst Properties

Reaction mechanisms and kinetic schemes

Effect of properties of solid materials on
their catalytic performance

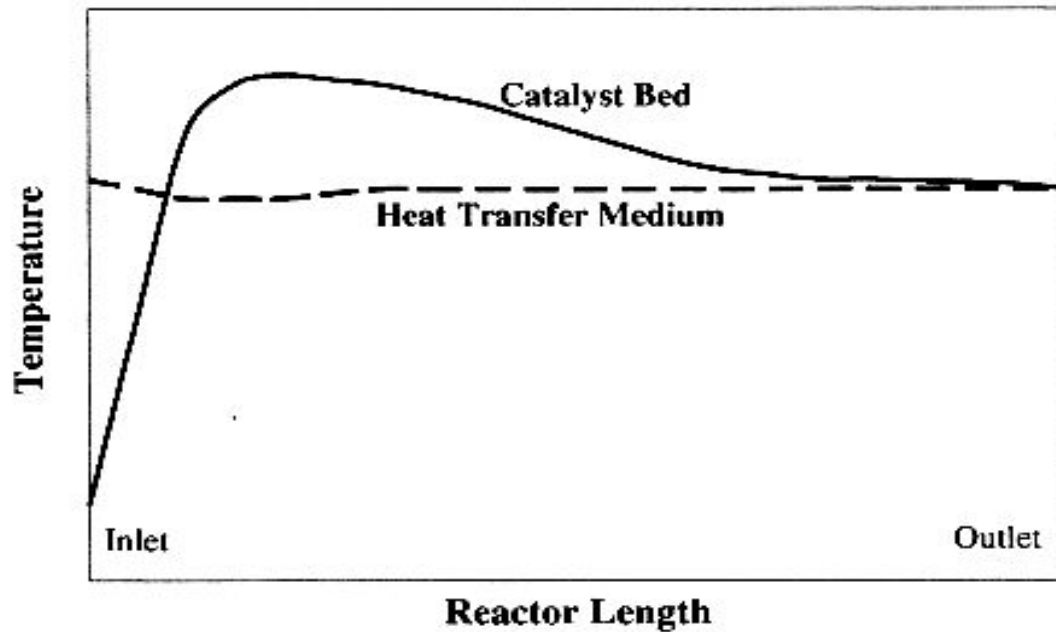

Subjects to be considered

- Interactions of gas-phase reactants with the catalyst surface, i.e., transformations of reactants on the catalyst surface
 - Solid state transformations in catalyst preparation and operation
 - Solid state properties
-

Reaction steps and kinetic schemes

- Single and multiple surface reaction steps (with and without intermediate desorption steps)
 - Parallel and consecutive reaction steps originating from one molecule influencing the selectivity of the desired product in such complex reaction networks as experienced in almost all hydrocarbon oxidation reactions.
 - Quantitative description of reaction schemes by rate equations of the various reaction steps and correlating the rate constants with catalyst properties
-

Temperature profile in and around a tubular continuous-flow catalytic reactor

Reaction Network in Selective Oxidation

Parallel and consecutive reactions

$$C = f(\tau); \quad S = f(X)$$

$$S_P = n_P / (n_{k,0} - n_k); \quad (v !!!)$$

$$X_k = (n_{k,0} - n_k) / n_{k,0}$$

$$Y_P = S_P \cdot X_k$$

Parallel and consecutive reactions

$$C = f(\tau); \quad S, Y = f(X)$$

$$S_P = n_P / (n_{k,0} - n_k); \quad (v !!)$$

$$X_k = (n_{k,0} - n_k) / n_{k,0}$$

$$Y_P = S_P \cdot X_k$$

Elucidation of reaction mechanisms

- solid state transformation in catalyst preparation and operation:
e.g. amorphicity, crystallinity, phase transformations,
 - solid state properties:
e.g. bulk and surface structure & composition, basicity/acidity,
el. conductivity, redox,
 - gas-phase reactants:
kinetic scheme
 - interactions between gas-phase reactants and catalyst
surface, i.e. transformation of reactants:
e.g. ad- & desorption, bond breaking and forming, atom
insertion & abstraction, ...
-

Effect of Anion Conductivity on C₂ Selectivity in OCM Reaction over CeO₂/CaO Catalysts

Effect of Oxygen Anion Conductivity on C₂ Selectivity for Different Oxides

Katalysator	lg σ_{ion} [$\Omega^{-1}\text{cm}^{-1}$]	S_{C_2+} [%]
ThO ₂	-7,06	25
Y ₂ O ₃	-6,91	42
Sm ₂ O ₃	-5,58	45
La ₂ O ₃	-5,67	55
Y ₂ O ₃ (5 Mol.-%)/ThO ₂	-5,32	54
Sm ₂ O ₃ (5 Mol.-%)/ThO ₂	-4,31	62
Sm ₂ O ₃ (10 Mol.-%)/ThO ₂	-3,99	62
La ₂ O ₃ (10 Mol.-%)/ThO ₂	-3,52	68
SrO(5 Mol.-%)/La ₂ O ₃ (10 Mol.-%)/ThO ₂	-3,37	71

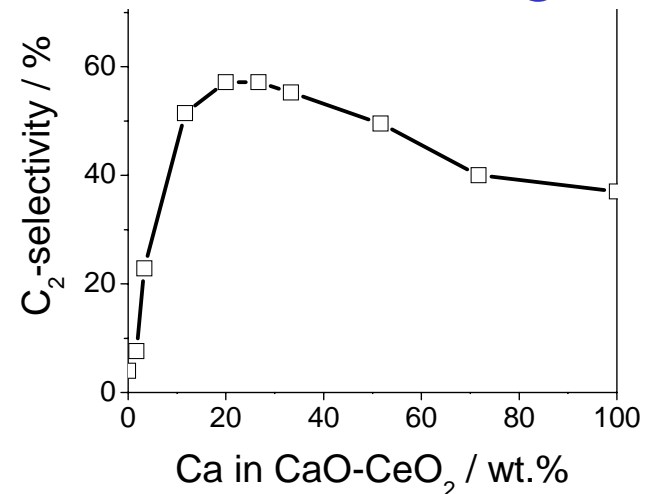

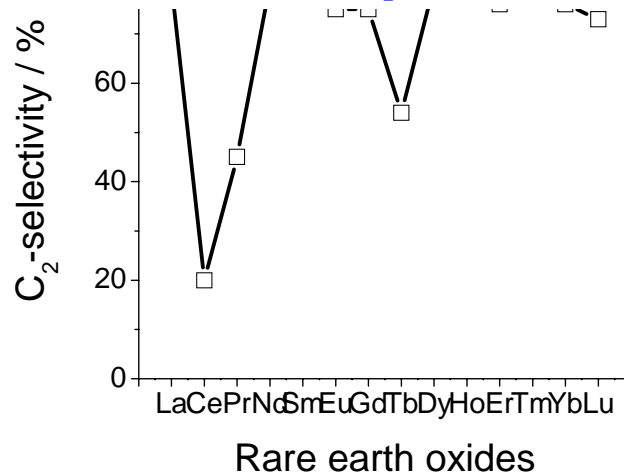

Effect of Electronegativity of different Oxides on C₂ Selectivity

Selectivity-determining factors in OCM - electronic properties of catalysts -

An optimized ratio of p-type to ionic-type conductivities is required for well-performing OCM catalysts

Scientific Knowledge on the OCM Catalysis

- **Co-feeding of O₂ and CH₄**
 - Basic catalytic materials are considered to be more efficient than the acidic ones (activation of C-H bond)
 - p-type semi-conductors are more selective than n-type ones. Band gap should be in the range of 5-6 eV.
 - An optimal ratio of p-type conductivity to O²⁻-conductivity is required (fast dissociation of adsorbed bi-atomic O species)
 - Structural point defects (anion vacancies, impurity transitional metal ions)
- **Periodic mode of operation**
 - High catalyst stability under reducing and oxidizing conditions
 - Catalyst ability for storing oxygen and offering high amounts of lattice oxygen
 - Minimal time of catalyst re-oxidation as compared to period of OCM reaction

Concluding Comments to OCM Catalysis

- In spite of all the extensive knowledge on OCM catalysis scientific breakthroughs are still required.
- Suppression of consecutive total oxidation of ethane and ethylene at high degrees of methane conversion

Yield Y of C_2 ($Y = S \cdot X / 100 \%$)

Presently $Y = 25 - 28 \%$

- This results in high expenditures for separation and recycle of

C_2H_6 / **C_2H_4** / **CH_4** / (CO_2 , CO)

making industrial application uneconomic

Part II

ODP

Oxidative dehydrogenation of propane to propene on different metal oxides (ODP)

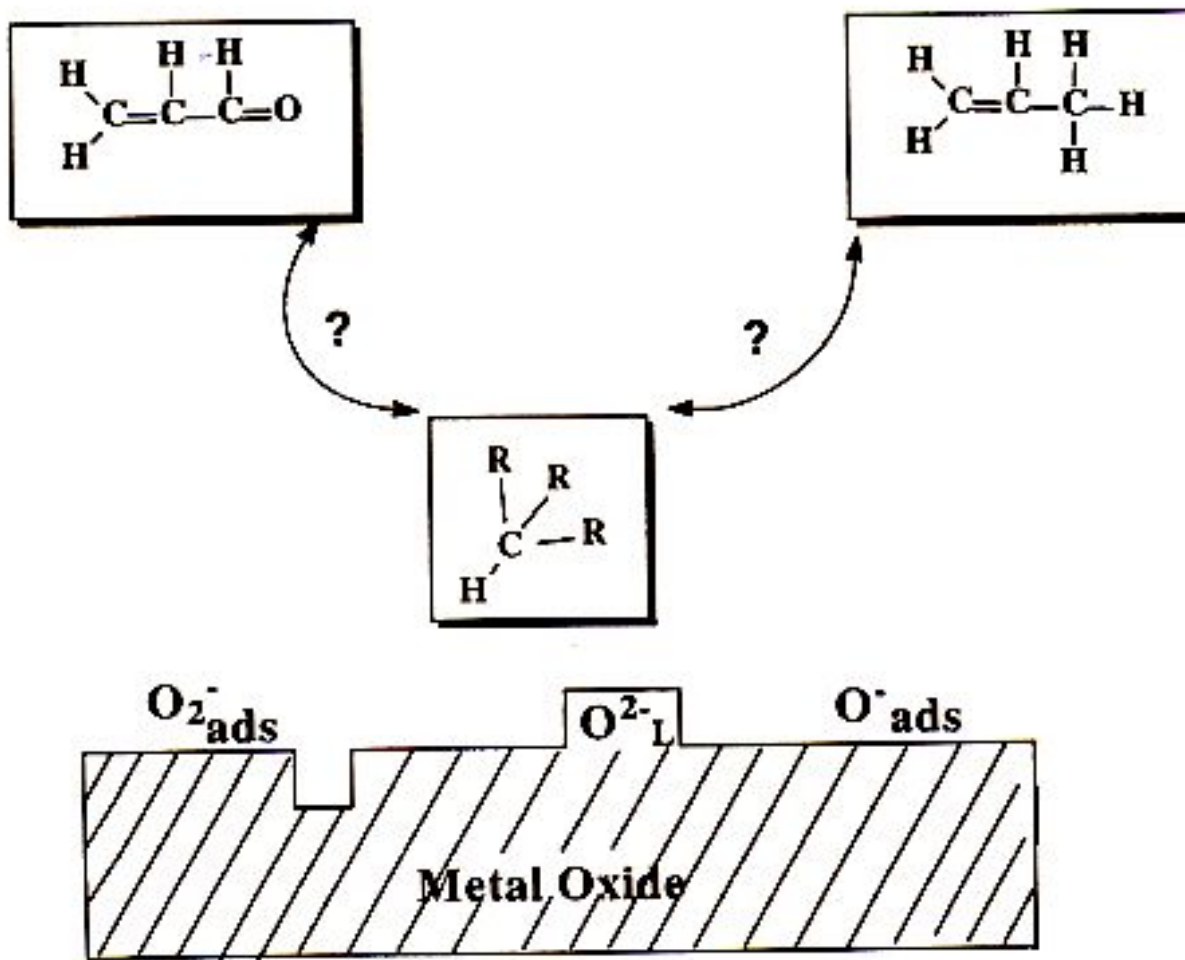

Overall Scheme of Oxidative Dehydrogenation of Alkanes to Olefins on Transition Metal Oxides Catalysts

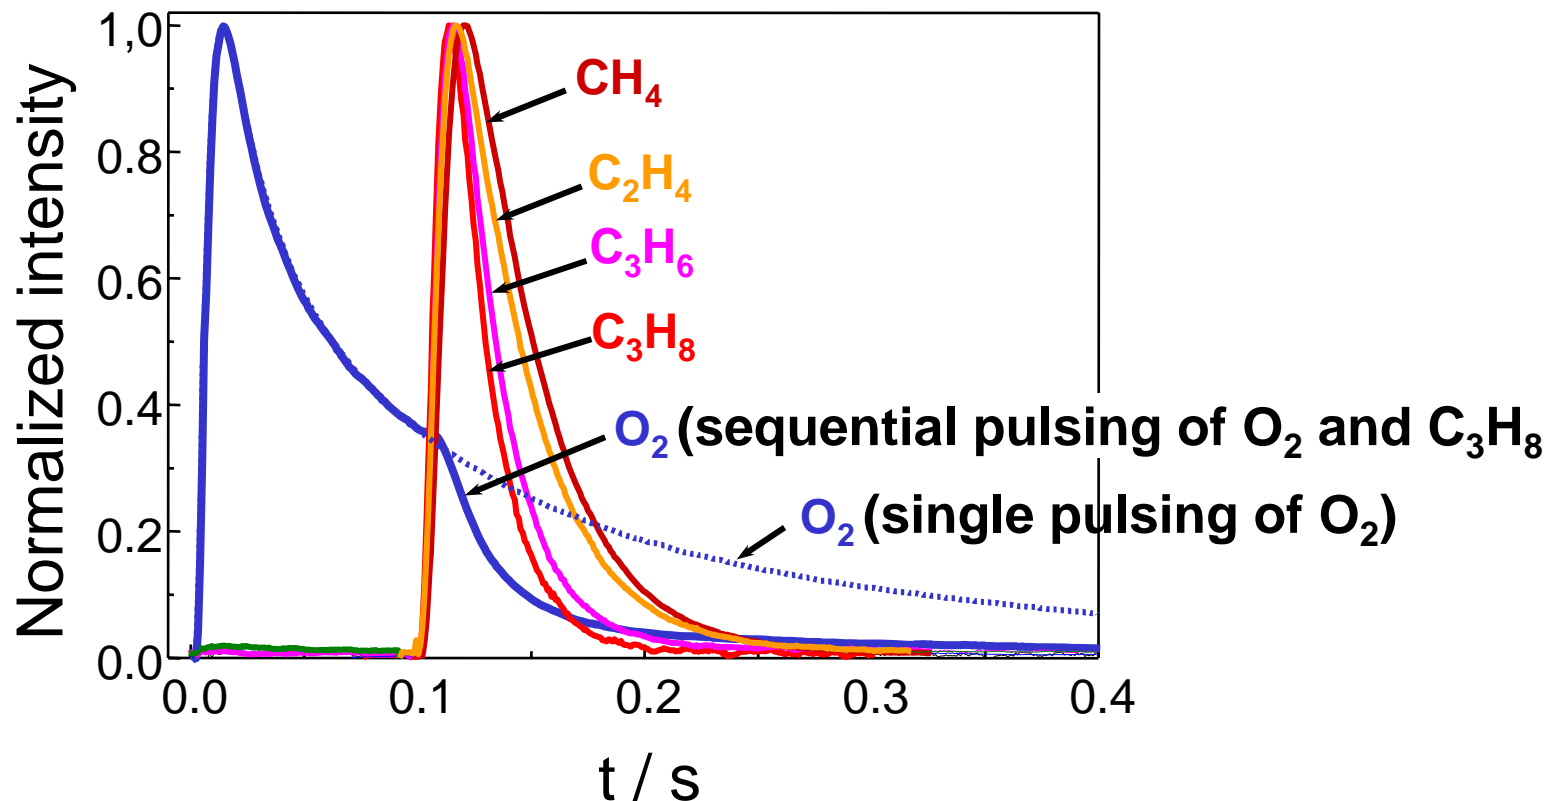

Selection of potential catalysts: Primary reaction steps of the oxidative dehydrogenation of alkanes on metal oxides

Interactions of an Alkane Molecule with a Catalytic Surface (different oxygen species)

Propane activation by adsorbed oxygen on $\text{SmNa}_{0.028}\text{P}_{0.014}\text{O}_x$ at 723 K

Reaction of propane with adsorbed oxygen species results in formation of propene followed by its further oxidation to ethylene and methane (besides CO_x)

Complex Mixtures of Metal Oxides as Potential Catalysts for Oxidative Dehydrogenation of Propane

Redox-metal oxides of medium metal-oxygen binding energy in the range -400 to -200 kJ/mol

Redox compounds: V_2O_5 Ga_2O_3 MoO_3

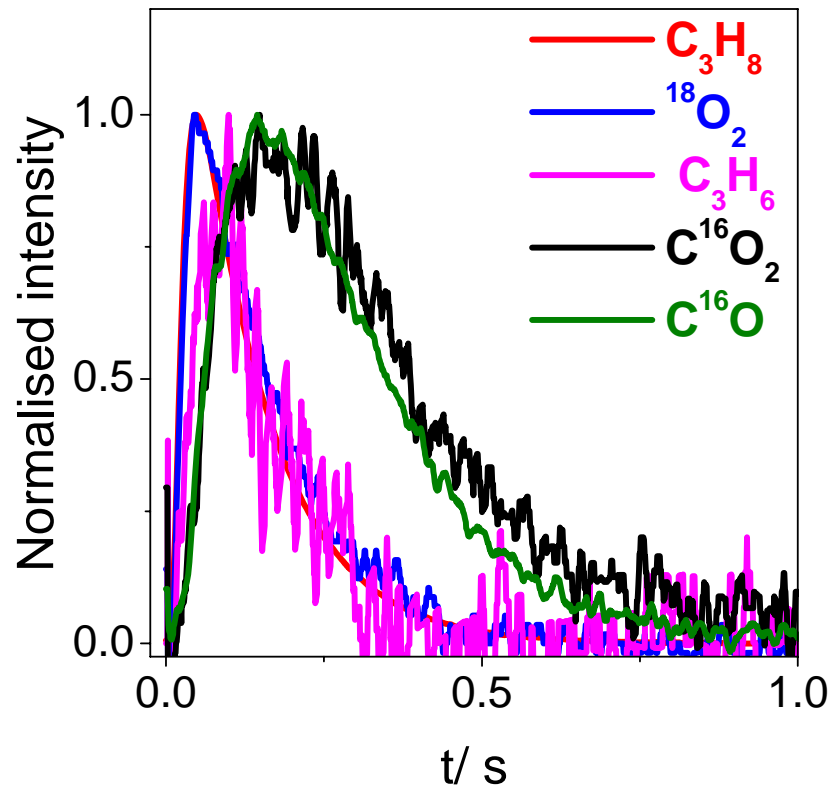

Support: MgO (basic metal oxide)

Detrimental to desired catalytic performance

- acidic metal oxide: B_2O_3
 - metal oxide, on which O_2 dissociates: La_2O_3
-

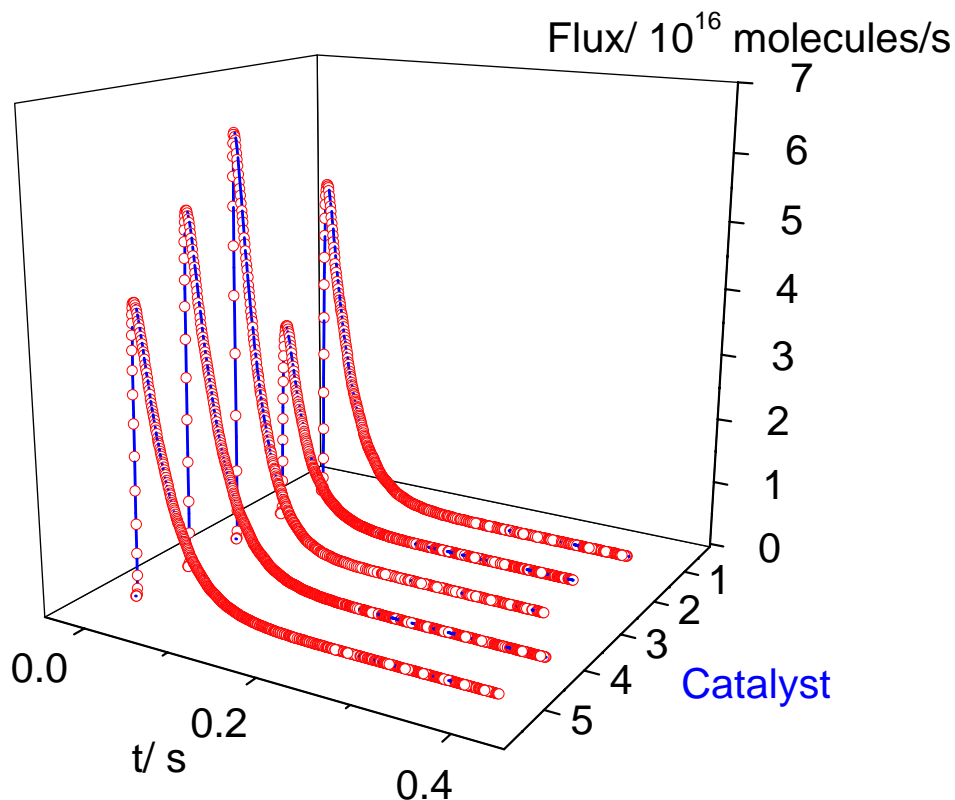

Propane activation by lattice oxygen

$^{18}\text{O}_2\text{-C}_3\text{H}_8$, $\text{V}^{16}\text{O}_x(9.5\%)/\gamma\text{-Al}_2\text{O}_3$, $T=798\text{ K}$

- No labeled (^{18}O) oxygen in CO_x products only lattice (^{16}O) oxygen is involved in the reaction
- Reaction sequence: $\text{C}_3\text{H}_8 \longrightarrow \text{C}_3\text{H}_6 \longrightarrow \text{CO} \& \text{CO}_2$
MvK mechanism

Kinetic evaluation and mechanistic assessment of oxygen transients

Model for O_2 activation

- 1 $V_{0.16}Mg_{0.11}Ga_{0.47}Mo_{0.17}Fe_{0.09}$
- 2 $V_{0.32}Mg_{0.18}Ga_{0.27}Mo_{0.04}Mn_{0.19}$
- 3 $V_{0.8}Mg_{0.2}$
- 4 $V_{0.2}Mg_{0.8}$
- 5 $V_{0.22}Mg_{0.47}Ga_{0.2}Mo_{0.11}$

Result: effective rate constant of O_2 activation/adsorption

- rate of formation of active lattice oxygen (regeneration) by gas-phase oxygen
- coverage by active lattice oxygen

$Y(\text{C}_3\text{H}_8)$ versus effective rate constant of O_2 activation determined from TAP experiments

- $\text{V}_{0.2}\text{Mg}_{0.8}$
- $\text{V}_{0.22}\text{Mg}_{0.47}\text{Ga}_{0.2}\text{Mo}_{0.11}$
- $\text{V}_{0.32}\text{Mg}_{0.18}\text{Ga}_{0.27}\text{Mo}_{0.04}\text{Mn}_{0.19}$
- $\text{V}_{0.16}\text{Mg}_{0.11}\text{Ga}_{0.47}\text{Mo}_{0.17}\text{Fe}_{0.09}$
- ▲ $\text{V}_{0.8}\text{Mg}_{0.2}$

Steady-state experiments

➔ $Y(\text{C}_3\text{H}_6)$ decreases with an increase in $k_{\text{ads}}^{\text{eff}}$
high concentration of near-surface lattice oxygen facilitates total oxidation

Mechanistic and Kinetic Aspects

- For the ODP reaction on vanadia-based catalysts, transient experiments proved that the dehydrogenation occurs by lattice oxygen via a Mars-van-Krevelen mechanism
- On non-transition metal oxides catalysts adsorbed oxygen plays a major role
- High concentrations of near-surface lattice oxygen as well as of adsorbed oxygen favour total oxidation

Characterisation of catalytic sites of vanadia-based catalysts

XPS & EPR: Relationship between catalytic performance and surface ratio of Mg/V

Reaction conditions: $C_3H_8-O_2-N_2=40-20-40$; $T=773K$; $X(O_2) \approx 100\%$

EPR measurements show increasing concentration of octahedral isolated VO^{2+} centres with increasing the Mg/V ratio (XPS). The more dispersed active vanadium species, the higher the selectivity that can be achieved.

EPR Spectra of VMgO catalysts

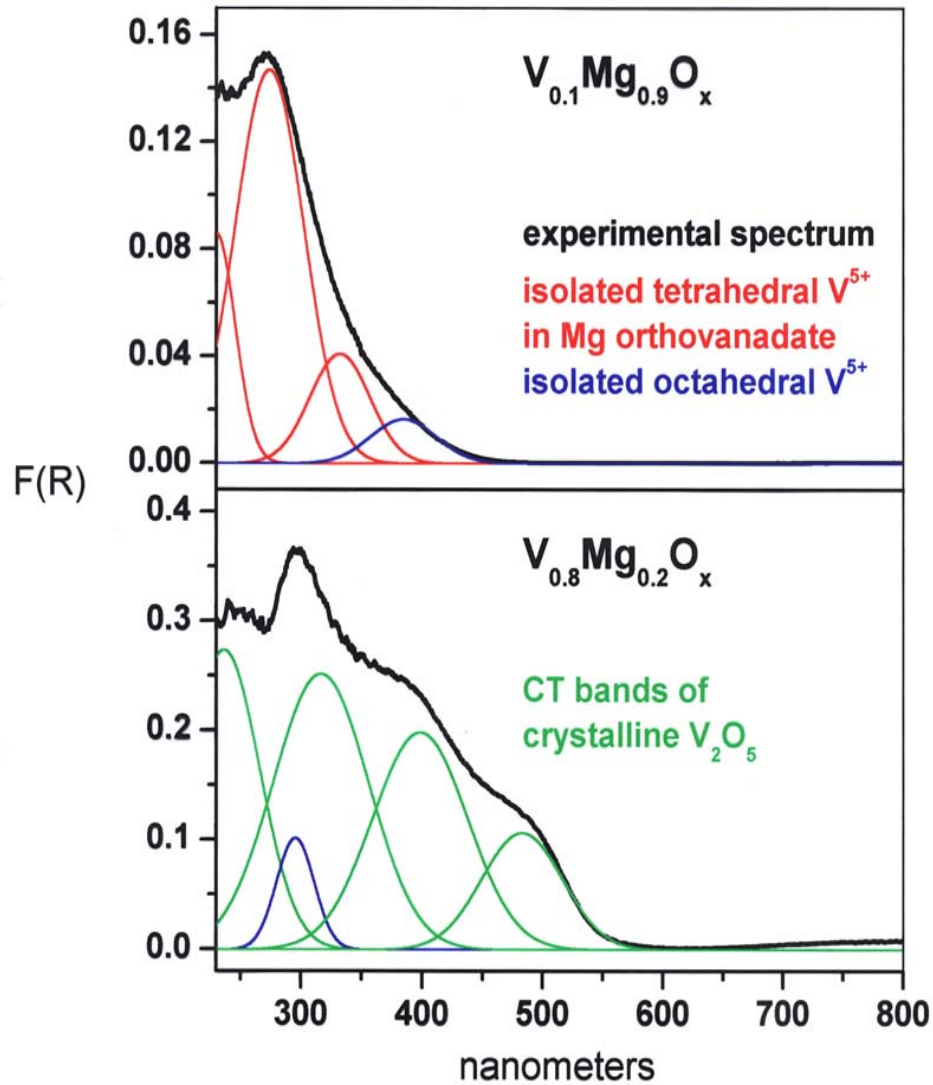

Isolated VO^{2+}

weakly interacting VO^{2+}

Strongly interacting VO^{2+}

UV/VIS-DRS spectra of VMgO catalysts

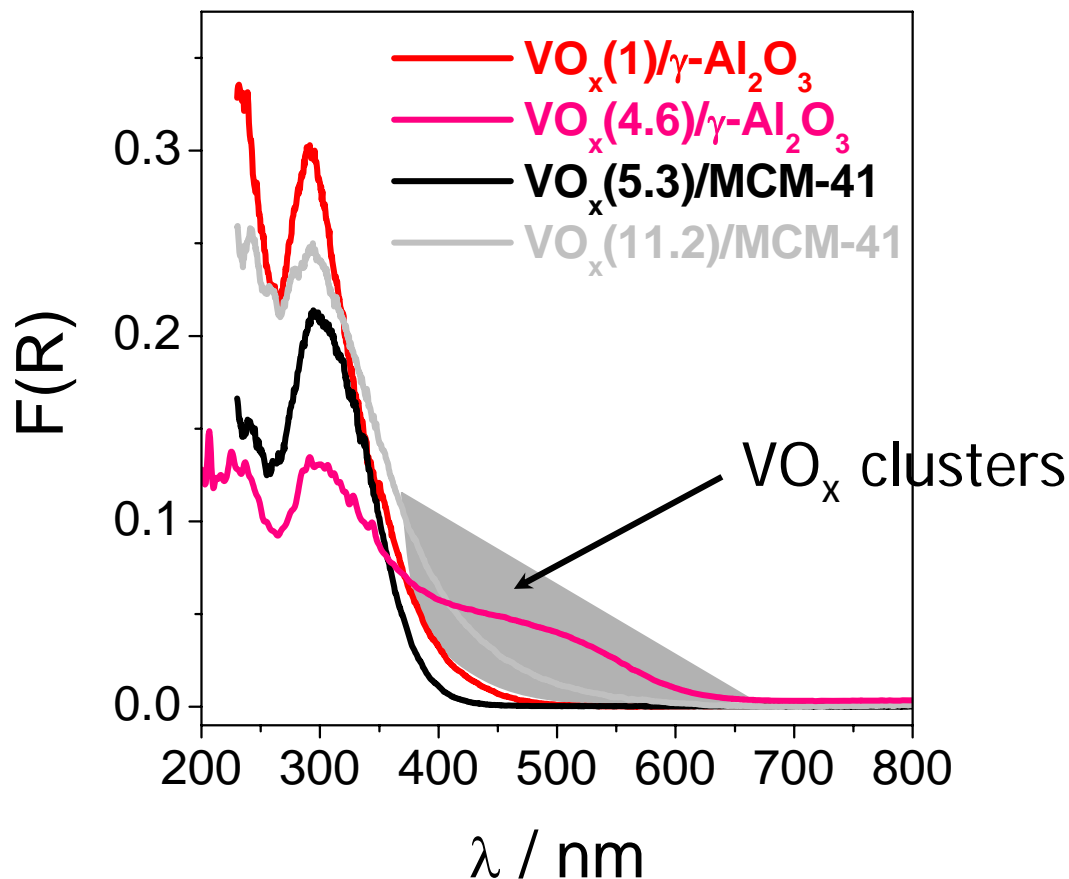

UV-vis spectra: Interaction of VO_x species of different materials at 773 K

No V-O-V bond !

Weak interaction between highly dispersed V^{5+}O_x species

UV-vis spectra: Interaction of VO_x species on different supports at 773 K

Degree of interaction (polymerisation) of V^{5+}O_x is a function of vanadia loading and the support material

Raman spectra: Identification of „sites“ on VO_x -loaded mesoporous MCM-41

- V_2O_5 phase is present at high vanadia loading
- Weakly interacting VO_x species exist under dehydrated conditions for samples with vanadia loading up to 4 to 5 wt.%

Conclusions for ODP

- **Operando UV-vis as well as EPR and in-situ Raman spectroscopy indicate the presence of highly dispersed vanadia in the form of monomeric and small 2-dimensional VO_x aggregates, which might be partly considered as isolated sites.**
- **The highly dispersed vanadia species contribute to selective oxidation while crystalline nanoparticles favour formation of carbon oxides**
- **Catalyst preparation: For achieving high selectivity of propene supported vanadia catalysts should be designed in such a way that preferentially weakly interacting VO_x species and preferably isolated sites are prepared.**
- **Reaction conditions: The concentration of near-surface lattice oxygen as well as of adsorbed oxygen should be low to avoid non-selective oxidation.**

What can be learnt?

From Elucidation of catalysis

—————→ improvement in

- understanding of interaction between reactant and catalyst
- catalyst development and optimization

From Kinetics of catalytic reaction

—————→ improvement in

- understanding of mechanistic aspects
- catalytic reaction-engineering procedures
