# Computation of Pore-Size Distribution in Terms of Surface Area 

B. VISWANATHAN and M. V. C. SASTRI<br>From the Department of Chemistry, Indian Institute of Technology, Madras, India

Received January 11, 1967; Revised April 4, 1967

#### Abstract

A simple method is suggested for computing pore-size distributions in terms of surface areas, instead of pore volumes, directly from low-temperature desorption isotherms of nitrogen. The method yields areas and distribution patterns which are very similar to those obtained with the BJH method, but the computational procedure is much simpler and can be handled conveniently with a conventional desk calculator.

Pore-size distribution data are becoming increasingly important in studies of heterogeneous catalysis, especially in the context of diffusion-controlled processes. In the more important pore-width range of 20 to $200 \AA$, the distribution is almost invariably obtained by mathematically tracking down the isothermal desorption of a capillary condensate, making use mainly of Kelvin's relation between equilibrium vapor pressure and capillary radius. Some of the more important methods of analysis, applicable to cylindrical pores,* have been reviewed by Wheeler (1). Of these, the most widely used method of computation is that originally developed by Barrett, Joyner, and Halenda (2) (BJH) and more recent modifications of it suggested by Pierce (3), Cranston and Inkley (4), and Dollimore and Heal (5). These involve cumulative compilation procedures which are tedious and time-consuming, unless they are either approximated at the expense of accuracy or handled with a digital computer.

A more direct approach for relating the differential amount of vapor desorbed ( $d V_{\mathrm{a}}$ ) with the differential volume of the pores emptied at any stage of the desorption has been suggested recently by Anderson (6). His method for deducing $V_{>R}$, though undoubtedly less tedious than the BJH method, uses another kind of "building

[^0]block" technique, involving three or four integrations. All these methods lead to poresize distributions in terms of the pore volumes only.

In this paper, a method is developed for computing the distribution of pore sizes in terms of surface area, which is more appropriate in the case of catalysts. Like the other methods, it is based on the model of the desorption process proposed originally by Wheeler (1), but the equation evolved is simpler for working with desk calculators.

## Solution for Area Distribution

The volume $V_{\mathrm{a}}$ of the adsorbate (reckoned as liquid volume) held by the solid at any point on the desorption isotherm is expressed by the equation (1)
$V_{\mathrm{a}}=V_{\mathrm{c}}\left(<R_{\mathrm{c}}\right)+t_{\mathrm{S}}\left(>R_{\mathrm{c}}\right)-\pi t^{2} L\left(>R_{\mathrm{c}}\right)$
where $V_{\mathrm{c}}\left(<R_{\mathrm{c}}\right)$ denotes the volume of all pores of radii smaller than $R_{\mathrm{s}}$ and hence filled with capillary condensate. The last two terms together give the geometric volume of the annulus of adsorbed vapor in wider pores. Differentiating this equation as such with respect to $R_{\mathrm{c}}$ we get

$$
\begin{align*}
& \frac{d V_{\mathrm{a}}}{d R_{\mathrm{c}}}=\frac{d V_{\mathrm{c}}\left(<R_{\mathrm{c}}\right)}{d R_{\mathrm{c}}}+t \frac{d S\left(>R_{\mathrm{c}}\right)}{d R_{\mathrm{c}}} \\
& +S\left(>R_{\mathrm{c}}\right) \frac{d t}{d K_{\mathrm{c}}}-\pi t^{2} \frac{d L\left(>R_{\mathrm{c}}\right)}{d R_{\mathrm{c}}} \\
& -\pi L\left(>R_{\mathrm{c}}\right) \frac{d\left(t^{2}\right)}{d R_{\mathrm{c}}} \tag{2}
\end{align*}
$$

Recognizing that, by definition,

$$
\begin{aligned}
V_{\mathrm{e}}\left(<R_{\mathrm{c}}\right) & =\int_{0}^{R_{\mathrm{e}}} \pi R_{\mathrm{c}}^{2} L\left(R_{\mathrm{c}}\right) d R_{\mathrm{c}} \\
S\left(>R_{\mathrm{c}}\right) & =\int_{R_{\mathrm{e}}}^{\infty} 2 \pi R_{\mathrm{c}} L\left(R_{\mathrm{c}}\right) d R_{\mathrm{c}}
\end{aligned}
$$

and

$$
L\left(>R_{\mathrm{c}}\right)=\int_{R_{\mathrm{c}}}^{\infty} L\left(R_{\mathrm{c}}\right) d R_{\mathrm{c}}
$$

and omitting the last term, containing $d\left(t^{2}\right) / d R_{\mathrm{c}}$, Eq. (2) reduces to*

$$
\begin{align*}
\frac{d V_{\mathrm{a}}}{d R_{\mathrm{c}}}=\frac{d S}{d R_{\mathrm{e}}}\left[\frac{t\left(R_{\mathrm{c}}-t\right)}{2 R_{\mathrm{e}}}-\right. & \left.\frac{\left(R_{\mathrm{e}}-t\right)}{2}\right] \\
& +\frac{d t}{d R_{\mathrm{c}}} S\left(>R_{\mathrm{c}}\right) \tag{3}
\end{align*}
$$

This being a linear differential equation it can be solved for $S$ in terms of $d V_{\mathrm{a}} / d R_{\mathrm{o}}$ and $d t / d R_{\text {c }}$. The solution may be expressed simply as

$$
\begin{equation*}
S\left(>R_{\mathrm{c}}\right)=h / g \tag{4}
\end{equation*}
$$

where

$$
\begin{align*}
h & =\int_{R_{\mathrm{e}}}^{\infty}\left(\frac{g}{x}\right)\left(\frac{d V_{\mathrm{a}}}{d R_{\mathrm{e}}}\right) d R_{\mathrm{e}}  \tag{4a}\\
g & =\exp \int_{0}^{R_{\mathrm{e}}} \frac{1}{x}\left(\frac{d t}{d R_{\mathrm{e}}}\right) d R_{\mathrm{c}} \tag{4b}
\end{align*}
$$

and

$$
\begin{equation*}
x=\left[\frac{t\left(R_{\mathrm{c}}-\ell\right)}{2 R_{\mathrm{c}}}-\frac{\left(R_{\mathrm{c}}-t\right)}{2}\right] \tag{4c}
\end{equation*}
$$

## Method of Computation

Values of the inner capillary radius ( $r_{\mathrm{k}}$ ) were computed from various relative pressures using the Kelvin equation

[^1]The negative sign of the last term, which is obviously wrong, has vitiated his solution for $S\left(>R_{\mathrm{o}}\right)$. Even when this error was corrected, it was found that dropping the last term in Eq. (1) before differentiation greatly impaired the accuracy of computation and raised the range of pore sizes accessible to it to 85 to $300 \AA$, thus leaving out the more important $r$ icropore region.

$$
\begin{equation*}
r_{k}(\AA)=\frac{-4.14}{\log _{10}\left(p / p_{0}\right)} \tag{5}
\end{equation*}
$$

The corresponding values of $t$, the thickness of the adsorbed multilayers on the pore walls, were determined by using Halsey equation (8) in the form given by Wheeler (1) for nitrogen and used by Dollimore and Heal (5), namely,

$$
\begin{equation*}
t(\AA)=-4.3\left[\frac{5}{\ln \left(p / p_{0}\right)}\right]^{1 / 3} \tag{6}
\end{equation*}
$$

Hence $R_{\mathrm{c}}=\left(r_{\mathrm{k}}+t\right)$ and $x$ [Eq. (4c)] could be obtained for each value of $p / p_{0}$ and therefore of $t$ (see Table 1, columns 1 to 5)

Next, to find $g$, the integral in Eq. (4b), which is the same as

$$
\int_{0}^{t}\left(\frac{1}{x}\right) d t
$$

was evaluated graphically from the plot of $1 / x$ vs. $t$. In this manner a master correlation chart or graph could be prepared giving $g /|x|$ values as a function of $p / p_{0}$ (Table 1 , cols. 1 and 7) which could apply universally to any adsorption data obtained with nitrogen at its normal boiling point.

The experimental data of $V_{\mathrm{a}}$ vs. $p / p_{0}$ could thus be transformed rapidly into one of $V_{\mathrm{a}}$ vs. $g /|x|$ as required by Eq. (4a).

In any actual case, all that one has to do, is to evaluate the integral in Eq. (4a). This can be done either graphically or numerically. The latter method with the aid of the trapezoidal rule was found to be more convenienl. Even one division of the interval between successive experimental values of $V_{\mathrm{a}}$ was found to be adequate to yield results comparable with those obtained by more elaborate methods. This is exemplified by the results presented in Table 2, which illustrates the method of computation outlined above. The experimental data used therein were obtained in this laboratory.

## Results and Conclusion

The method outlined above was also applied to data obtained on a variety porous solids by other workers. A comparative statement of the cumulative areas derived by different methods is given in Table 3. The area values obtained with the help of

Eq. (4) of this paper are seen to be generally in good agreement with those found by the BET and the BJH methods. The distribution plots, $\Delta S / \Delta R_{\mathrm{c}}$ vs. $R_{\mathrm{c}}$, are also very similar in form to those derived by the BJH method, as may be seen from a typical example shown in Fig. 1.

To summarize, the advantages claimed for the method suggested in this paper are mainly the following:

1. The computational procedure is much simpler, speedier, and more suited to handling with small desk calculators than the BJH and other methods reported hitherto. At any stage of the computation, the total surface area up to that point can be obtained directly without going through the tedious summing up sequences of the BJH method and its modifications (2-5).
(2) The pore-size distribution is obtained
